

Appendix I

Evaluation of Tailings Mixing in Chaparral Gulch and the Tailings Floodplain

Appendix I

Evaluation of Tailings Mixing in Chaparral Gulch and the Tailings Floodplain

This appendix evaluates where tailings from the former Iron King Mine property have contributed to the presence of tailings in the sediment of the Tailings Floodplain and Chaparral Gulch on the former Humboldt Smelter Property upstream of the Chaparral Gulch Dam. The primary potential sources of impacts to the Chaparral Gulch and Tailings Floodplain system are tailings associated with former Iron King Mine operations that migrated from the Main Tailings Pile (MTP) (primarily as a result of the 1964 MTP Blow Out) and the former Small Tailings Pile (which was removed and consolidated with the MTP in 2011), and tailings associated with operations at the former Humboldt Smelter property.

Potential transport mechanisms for these materials include:

- Direct discharges of water with high particulate loads during active periods of operation at the former Iron King Mine and former Humboldt Smelter properties
- Direct releases of tailings associated with failures of tailings impoundments
- Erosion of previously placed tailings and downstream sediment transport to and within Chaparral Gulch
- Accumulation of windblown tailings in the Chaparral Gulch watershed and subsequent erosion and downstream sediment transport to and within the gulch

Tailings-impacted sediment has accumulated upstream of the Chaparral Gulch Dam. While aerial photographic interpretation constrains the timing of significant downslope movement of tailings from the Smelter Tailings Swale into the Tailings Floodplain on the former Humboldt Smelter property, the volume of tailings upstream of the dam appears to be larger than could have been stored in the Smelter Tailings Swale. Operations at the former Humboldt Smelter property appear to have used the Tailings Floodplain for additional storage of tailings early in the operations history, but lead and zinc concentrations in some tailings samples from the floodplain area are substantially higher than in tailings exposed in the Smelter Tailings Swale that originated from former Humboldt Smelter property. Tailings from the former Iron King Mine property have elevated lead and zinc concentrations relative to the tailings associated with former Humboldt Smelter property and are interpreted to be a potential source of the additional tailings observed upstream of the dam.

Objective

The objective of this evaluation was to assess whether tailings associated with the former Iron King Mine property mixed with sediment and tailings from the former Humboldt Smelter property that have accumulated in the Tailings Floodplain and Chaparral Gulch upstream of the Chaparral Gulch Dam. The differentiation of tailings from the former Iron King Mine and Humboldt Smelter properties is based on physical characteristics (color for example) and relative metals concentrations. However, differentiation of these tailings is complicated by mixing, redeposition, and other sediment transport processes, which can alter the physical characteristics. Therefore, a statistical comparison of key metals and ratios of metals was used to assess whether tailings from the former Iron King Mine contributed to these deposits.

Recent and Quaternary Deposits in Chaparral Gulch

During the data gap phase of the remedial investigation, the U.S. Environmental Protection Agency installed 115 borings within and adjacent to the Chaparral Gulch channel and the Tailings Floodplain (Lockheed Martin SERAS, 2015). At most locations, the borings were advanced through the recent and Quaternary deposits that fill the gulch into the underlying Hickey Formation.

Six unconsolidated units (also referred to as hydrostratigraphic units) were observed and mapped in the subsurface. These included recent materials deposited after the Iron King Mine and Humboldt Smelter began operations, and older pre-existing materials that existed before these operations began. The units observed were as follows:

- Materials deposited after operations began at the former Iron King Mine and Humboldt Smelter properties:
 - Uppermost Channel Deposit (UCD)
 - Tailings
 - Humboldt Smelter Channel Deposit (HSCD)
 - Lowermost Channel Deposit (LCD)
- Materials deposited before operations began at the former Iron King Mine and Humboldt Smelter properties:
 - Brown Clay
 - Principle Fluvial Gravels (PFG)

These unconsolidated sediments are underlain by the Hickey Formation.

The characteristics of the recent materials are as follows:

- The UCD, HSCD, and LCD are interpreted to consist of mixed tailings and fluvium based on their stratigraphic position, physical characteristics, and elevated metals concentrations (Lockheed Martin SERAS, 2015). These were deposited after the operations began at the former Iron King Mine and Humboldt Smelter properties.
- The Brown Clay and PFG were interpreted to be native alluvium and are generally not impacted by Site contamination. These were deposited before operations began at the former Iron King Mine and Humboldt Smelter properties.
- Tailings in and around Chaparral Gulch are described as “HS” tailings based on their proximity to the former Humboldt Smelter property, but are not necessarily exclusive in origin to the Smelter Tailings Swale, as will be shown below. Both undisturbed and reworked (such as redeposited and mixed) tailings have been observed in the subsurface of Chaparral Gulch.

The UCD extends from the NR5 MTP Blow Out Path to the Smelter Tailings Swale where it thins to surface veneer. The LCD, HSCD, and tailings deposits extend from the Smelter Tailings Swale to the Chaparral Gulch Dam. Tailings deposits from the former Iron King Mine property also are interpreted to occur in Chaparral Gulch upstream of the Smelter Tailings Swale and in Chaparral Gulch downstream of the Smelter Tailings Swale to the dam (Tailings Floodplain) based on the findings of this evaluation.

Technical Approach

Analytical data for the tailings samples collected from the former Iron King Mine property (labeled as “IKM Tailings” in the tables and figures of this appendix) and the Smelter Tailings Swale (labeled as “HS Tailings” in the tables and figures of this appendix), as well as the UCD, LCD, HSCD, and other

unconsolidated deposits in Chaparral Gulch upstream of the dam were compiled and categorized by unit or material (for example, Iron King Mine tailings, UCD, Brown Clay, etc.). Afterward, exploratory analysis was performed to identify geochemical signatures that most clearly differentiate Iron King Mine tailings from Humboldt Smelter tailings. At the former Iron King Mine property, a massive sulfide deposit was exploited that primarily produced lead and zinc (and some copper); the concentrations of these metals remain elevated in Iron King Mine tailings. Smelter operations at the former Humboldt Smelter property processed copper; the Humboldt Smelter tailings are concentrated in copper relative to other metals. Consequently, the concentrations of lead, zinc, and copper, as well as the ratios of lead to copper ($Pb:Cu$) and zinc to copper ($Zn:Cu$) concentrations, were used for the comparative statistical analysis of the samples from these sources and the geologic groupings for Chaparral Gulch. Finally, each of the samples for all material types was scored on the basis of how close its chemical properties resembled Iron King Mine tailings. After scoring, figures were developed to illustrate the spatial distribution of the samples for each material group and how closely they resembled tailings from the Iron King Mine property.

Statistical Analysis

The following statistical tools were used to evaluate the presence of tailings that potentially could be derived from the former Iron King Mine property:

- **The Wilcoxon Rank Sum Comparison (WRS):** The WRS is a non-parametric method used to compare two samples and determine if they are drawn from populations with different means (Gilbert, 1987). The WRS was used to test whether the $Pb:Cu$ and $Zn:Cu$ for Iron King Mine tailings (from the MTP) and Humboldt Smelter tailings (from the Humboldt Smelter Tailings Swale) were significantly different, and therefore is useful for differentiating these sources. In addition, WRS tests were performed to compare the ratios for the other geologic groupings to those of the Iron King Mine and Humboldt Smelter tailings.
- **Box and Whisker Plot (BWP):** BWPs provide a visual idea of central tendency, variability, and skewness of each dataset for comparison (Swan and Sandilands, 1995). BWPs are used to assess differences in the concentrations of lead, copper, and zinc, as well as the concentration ratios between the two sources (former Iron King Mine and Humboldt Smelter properties), and potential influence of one source over another in mixtures (that is, geologic groupings for Chaparral Gulch).
- **Normality Quantile Plot (NQP):** The NQP is commonly used in testing the normality of a sample set, with a perfectly normal distribution plotting as a straight line (Gilbert, 1987). NQPs are also useful for visually comparing characteristics of sample distributions. NQPs were used to infer differences among the sample groupings and the degree of contribution (mixing) between sample groups based on distribution of their $Pb:Cu$ and $Zn:Cu$ ratios.

Spatial Distribution Analysis

The following tools were used to evaluate the distribution of tailings potentially from the former Iron King Mine property:

- **Cross Plots:** Cross plots were developed for lead and copper concentrations versus zinc concentrations, along with the $Pb:Cu$ and $Zn:Cu$ ratios on an alternate y-axis. Concentrations and ratios were color coded for each of the material types (tailings sources and sediments in Chaparral Gulch) to allow a visual examination of how the populations of data compare to Iron King Mine tailings. The cross plots are log-log in scale, providing the advantage to view data of a broad range of scales, which allows for an examination of data clustering between material types.
- **Ranking:** Each of the samples for each of the material types was scored over a range of 1 to 7 with how closely they resembled Iron King Mine tailings: 1 being best and 7 being worst. After scoring,

figures were developed to illustrate the spatial distribution of the samples for each material group. A composite map also was developed to illustrate the combined spatial distribution for the materials deposited after operations began at the former Iron King Mine and Humboldt Smelter properties. The plots show the distribution of materials likely derived from the former Iron King Mine property.

Findings

This section describes the findings from the statistical analysis and evaluation of the spatial distribution of contaminants in the tailings.

Statistical Analysis

The findings of the statistical evaluation are presented in the following tables and figures:

- Table I-1 presents zinc, copper, and lead concentrations and their concentration ratios
- Table I-2 presents the WRS results for Pb:Cu ratios and their mean and median values
- Table I-3 presents the WRS results for Zn:Cu ratios and their mean and median values
- Figures I-1a through I-1e show the BWPs for copper, zinc, and lead concentrations and their concentration ratios
- Figures I-2a through I-2e show the NQPs for Pb:Cu ratios
- Figures I-3a through I-3e show the NQPs for Zn:Cu ratios

All analytical data were used for the statistical analysis, including duplicates. The results are discussed below.

Wilcoxon Rank Sum Comparisons

Tables I-2 and I-3 summarize the results of the WRS test with respect to Pb:Cu and Zn:Cu ratios, respectively, for both the Iron King Mine and Humboldt Smelter tailings. Each table is organized into two groups of materials: (1) those that were deposited after operations began at the former Iron King Mine and Humboldt Smelter properties, and (2) those that were in place prior to Iron King Mine and Humboldt Smelter operations. The fourth column of each table shows the probability that differences between the two groups occurs by chance (that is, they are part of the same population). In this kind of test, a probability of greater than 0.05 would indicate that they are not significantly different at the 95 percent confidence level. Relevant findings from the WRS comparisons are summarized below:

- The mean Pb:Cu and Zn:Cu ratios for Iron King Mine tailings are, 35.3 and 71.1, respectively. The mean ratio values are larger than all other geologic groupings except the Pb:Cu for the reworked tailing group, which is slightly larger (42).
- The mean Pb:Cu and Zn:Cu ratios for Humboldt Smelter tailings are 1.93 and 5.67, respectively.
- The mean Pb:Cu and Zn:Cu ratios for other impacted units (UCD, LCD, and HSCD) are intermediate between those of the Iron King Mine tailings and Humboldt Smelter tailings.
- The probability that the Pb:Cu and Zn:Cu for the Iron King Mine tailings and Humboldt Smelter tailings are the same is small, on the order of 10^{-12} for both Pb:Cu and Zn:Cu ratios. Based on this analysis, the Pb:Cu and Zn:Cu ratios for these materials are statistically distinct. In addition, the Pb:Cu and Zn:Cu ratios for the Iron King Mine tailings are different than the ratios for all other geologic groupings.
- The Pb:Cu and Zn:Cu ratios for the Humboldt Smelter tailings are similar (with no significant difference) to those of the HSCD (impacted), Brown Clay (not impacted), and PFG (not impacted). In

addition, the Pb:Cu ratios for the Humboldt Smelter tailings are similar to those of the Hickey Formation.

This analysis confirms that the Pb:Cu and Zn:Cu ratios of the Iron King Mine tailings are statistically different (larger) than those from those for Humboldt Smelter tailings, and are therefore useful geochemical signatures to distinguish contributions of Iron King Mine tailings in Chaparral Gulch from those caused by Humboldt Smelter tailings. On a related note, the Humboldt Smelter tailings are statistically similar to non-mine related deposits, demonstrating that only the Iron King Mine tailings contain elevated lead and zinc in comparison to copper levels.

Box and Whisker Plots

The BWPs were prepared for each of the hydrostratigraphic units for Pb:Cu and Zn:Cu ratios, as well as lead, zinc, and copper concentrations. In each case, two sets of plots were prepared: one incorporating all data, and a second that removes elevated outlier results to allow for improved review of the main body of data. Figures I-1a through I-1e show the BWPs for copper, lead, and zinc concentrations along with the Pb:Cu and Zn:Cu ratios.

For the BWP, data values are plotted on the y-axis; the x-axis has no value, but instead the BWPs are distributed much like in a histogram. The following properties are displayed:

- The height of the box represents the interquartile range (IQR). The IQR is the distance between the 25th and the 75th percentiles.
- The horizontal line in the box interior represents the median.
- The vertical lines issuing from the box (the “whiskers”) extend to the minimum and maximum measured values (or 1.5 times the IQR, whichever is lower).
- Individual data symbols (asterisks in this case) are used for concentrations that exceed the whiskers (that is, they are either greater than 1.5 times the IQR or less than the IQR/1.5). These are often described as outliers, although they should not be interpreted as suspected erroneous data points, but rather as more extreme values compared to the main body of data.

Observations from the BWPs are summarized below:

- Although there is some degree of overlap among the groups, the BWPs show that median concentrations of lead, copper, and zinc are higher in Iron King Mine tailings than in Humboldt Smelter tailings, while copper is the dominant metal in the Humboldt Smelter tailings. There is clear separation in concentrations for lead and zinc between the two groups of tailings, making these good indicators of Iron King Mine tailings impacts. There is overlap in concentration for copper, making it a less useful indicator of Iron King Mine tailings impacts.
- Of the impacted geologic groups, the median concentration of lead and zinc are highest and the IQR of concentrations largest for the reworked tailings, while the median concentration of copper was larger in the undisturbed tailings. The median lead concentration for the reworked tailings actually exceeds that for the Iron King Mine tailings.
- The majority of the Pb:Cu and Zn:Cu ratios for Iron King Mine tailings exceed those of the Humboldt Smelter tailings, and there is very little overlap of the IQR for these groups, which is consistent with the findings of WRS comparisons.
- The reworked tailings have higher median Zn:Cu and Pb:Cu ratios and larger IQRs of these ratios than the undisturbed tailings, the Humboldt Smelter tailings from the Smelter Tailings Swale, and the other impacted units in the gulch. In addition, there is substantial overlap between the Zn:Cu and Pb:Cu IQRs for the Iron King Mine tailings and reworked tailings, and the median Pb:Cu ratio for the reworked tailings is actually higher than for the Iron King Mine tailings.

The Zn:Cu and Pb:Cu ratios of the reworked tailings (and the UCD) are higher than those for the Humboldt Smelter tailings. The higher ratios are consistent with source or contribution of Iron King Mine tailings to Chaparral Gulch. The median Pb:Cu ratio for the reworked tailings is higher than for the Iron King Mine tailings, but ratios for the Humboldt Smelter are almost completely below the range of the Iron King Mine tailings.

Lead is the most resistant to leaching of the three metals evaluated. One possible explanation for the higher median ratios in the reworked tailings is preferential leaching of copper versus lead during transport and after deposition in the gulch. The median lead concentration for the Iron King Mine tailings is higher than for the reworked tailings; thus, the higher ratios in the reworked tailings do not appear to be caused by enrichment of lead relative to source material that originates from former Iron King Mine property.

Normality Quantile Plots

For the NQPs, the y-axis is the concentration or ratio; the x-axis is the normal quantile or Z-statistic, which splits the number of samples into roughly equal numbers arranged by distance from the median (negative indicates below the median and positive above). Figures I-2a through I-2e show the NQPs for Pb:Cu ratios, and Figures I-3a through I-3e show the NQPs for Zn:Cu ratios. Note that the blue points represent data for Iron King Mine tailings, the red points represent the data for Humboldt Smelter tailings, and the green points represent data for individual geologic units. Groups with a similar distribution of ratios would plot close together on an NQP. Groups containing mixtures of Iron King Mine and Humboldt Smelter tailings would plot between the two end-member distributions.

Observations from the NQPs are summarized below:

- The undisturbed tailings plot relatively close to the Humboldt Smelter tailings for both Zn:Cu and Pb:Cu ratios, suggesting little if any contribution from the Iron King Mine tailings. The data for the HSCD show similar trends.
- The reworked tailings show elevated Zn:Cu ratios that fall midway between the distribution of the Iron King Mine and Humboldt Smelter tailings. At high values, the ratios for the reworked tailings are nearly equivalent to those of the Iron King Mine tailings, suggesting a strong contribution of Iron King Mine tailings in these materials.
- For Pb:Cu ratios, the reworked tailings plot along the Iron King Mine tailings at the lower concentrations, then deviate to higher Pb:Cu ratios above the median. As discussed above, the anomalous high Pb:Cu ratios in the reworked tailings may have been caused by preferential leaching of copper versus lead during transport in the gulch.
- For the UCD, the Zn:Cu and Pb:Cu ratios plot between the data for Humboldt Smelter tailings and Iron King Mine tailings, suggesting mixing with Iron King Mine tailings. Note that there is no significant difference between the ratios for the Humboldt Smelter tailing and the native deposits (Brown Clay and PFG). The plot actually reflects mixing with native material rather than Humboldt Smelter tailings, as the UCD largely occurs upstream of the Tailings Swale. The data for LCD show similar trends.

These plots further demonstrate the source contribution of Iron King Mine tailings to floodplain sediment upstream of the Chaparral Gulch Dam. The reworked tailings, UCD, and LCD all appear to contain Iron King Mine tailings. The undisturbed tailings and HSCD have ratio characteristics similar to those of Humboldt Smelter tailings. There appears to be little Iron King Mine tailings source contribution in these materials.

Spatial Distribution Analysis

The findings of the spatial distribution analysis are presented in the following tables and figures:

- Attachment I-1 (Figures I-1-1a through I-1-1l) provides the cross plots of zinc concentrations versus lead and copper concentrations and the Pb:Cu and Zn:Cu ratios. Figure I-1-1a illustrates the data for all material groups, Figure I-1-1b highlights the data for Iron King Mine tailings, Figure I-1-1c illustrates the “cut points” used for the ranking analysis (explained below), and Figures I-1-1d through I-1-1l illustrate the Iron King Mine tailings data versus the data for each of the other material types.
- Tables I-4 and I-5 rank the materials for each sample with how closely they resemble Iron King Mine tailings. Table I-4 sorts the ranking by material type, and Table I-5 sorts by sample location.
- Figure I-4 illustrates the distribution of samples for Iron King Mine tailings in the MTP for the combination of lead and zinc signatures. All of the samples have a ranking of “1”.
- Figure I-5 illustrates the distribution of samples for materials in the Smelter Tailings Swale, Chaparral Gulch, and the Tailings Floodplain to the dam. The samples for the recent materials deposited after operation of the Iron King Mine and Humboldt Smelter began are ranked from “1” through “7” (tailings and channel deposits). The materials deposited before Iron King Mine and Humboldt Smelter began operations are given a gray color because they are not impacted by the mining operations and are all ranked “7”.
- Figures I-6a through I-6j illustrate the distribution of samples in Figure I-5, broken by material type.

Analytical data for duplicates were omitted from the spatial distribution analysis. The results are discussed below.

Cross Plots and Ranking

Based on examination of the cross plots, it was determined that Iron King Mine tailings had the following unique attributes compared to the other material types, including Humboldt Smelter tailings (Attachment I-1, Figures I-1-1b and I-1-1c):

- Lead concentrations were greater than 1,000 milligrams per kilogram (mg/kg), while the other material types were less.
- Zinc concentrations were greater than 1,000 mg/kg, while the other material types were less.
- Pb:Cu ratios were greater than 6, while the other material types were less.
- Zn:Cu ratios were greater than 20, while the other material types were less.

The tailings from the Iron King Mine are a clear end-member for these four parameters (especially lead and zinc concentrations and to a slightly lesser degree the two ratios) compared to the other material groups, and therefore a powerful tool to identify these tailings mixed with the other materials, including Humboldt Smelter tailings. Copper was not a useful attribute to distinguish Iron King Mine tailings from Humboldt Smelter tailings because the copper concentration ranges overlapped. Therefore, the Pb:Cu and Zn:Cu ratios were also slightly less useful than the simple lead and zinc concentrations to distinguish Iron King Mine tailings from Humboldt Smelter tailings, although the ratios were still useful.

Each of the samples for each of the material types were scored over a range of 1 to 7 with how close they resembled Iron King Mine tailings, with 1 being best and 7 being worst (Tables I-4 and I-5). A score of 1 was given if both lead and zinc were greater than 1,000 mg/kg, indicating high confidence that the material was from Iron King Mine. A score of 2 was given if each of the concentrations was greater than 900 mg/kg, indicating that some mixing with materials not from Iron King Mine could have occurred.

APPENDIX I
EVALUATION OF TAILINGS MIXING IN CHAPARRAL GULCH AND THE TAILINGS FLOODPLAIN

Scores of 3, 4, 5, 6, and 7 were given if the concentrations were greater than 800, 700, 600, 500, and 0 mg/kg, respectively. The range from 500 to 0 mg/kg was not further broken down because this encompasses the range of concentrations for Humboldt Smelter tailings and would not provide value in distinguishing between the two material types. The scoring was repeated to also include the two ratios, in addition to lead and zinc concentrations.

The scoring ranges for the zinc and lead concentrations, and the two ratios, are as follows. A color was also assigned to facilitate visual analysis with evaluating the spatial distribution of the scores:

Score	Color	Zinc (mg/kg)	Lead (mg/kg)	Zn/Cu (ratio)	Pb/Cu (ratio)
1	Red	>1000	>1000	>20	>6
2	Orange	>900	>900	>18	>5.5
3	Yellow	>800	>800	>16	>5
4	Light Green	>700	>700	>14	>4.5
5	Blue	>600	>600	>12	>4
6	Light Blue	>500	>500	>10	>3.5
7	Grey	>0	>0	>0	>0

The results from the ranking analysis are consistent with the results from the statistical analysis. The ranking analysis show the following:

- Materials in the Smelter Tailings Swale (Humboldt tailings and HSCD) are distinctly different in chemical signature (lead and iron concentrations and Pb:Cu and Zn:Cu ratios) compared to the Iron King Mine tailings (Attachment I-1, Figures I-1-1d and I-1-1e). These materials are given a rank of 7. This is consistent with the statistical analysis above.
- Materials logged as channel deposits (UCD, LCD) and tailings (reworked, undisturbed) are variably similar or dissimilar in chemical signature compared to the Iron King Mine tailings (Attachment I-1, Figures I-1-1f through I-1-1i). Materials most resembling Iron King Mine tailings are given a rank of 1 and those least resembling Iron King Mine tailings are given a rank of 7. A portion of samples for each of these material groups was given a rank of 1, indicating Iron King Mine tailings presence. The UCD and upper tailings classified as reworked were given the highest percentage of high ranks while the LCD and lower tailings classified as undisturbed were given the lowest percentage of high ranks, indicating that Iron King Mine tailings were preferentially present in the UCD and reworked tailings compared to the deeper undisturbed tailings and LCD. This is consistent with the statistical analysis above.
- Materials logged as Brown Clay, PFG, and Hickey Formation (ash/cinder or conglomerate) are distinctly different in chemical signature compared to the Iron King Mine tailings (Attachment I-1, Figures I-1-1j and I-1-1l). These materials are given a rank of 7. This is consistent with the statistical analysis above.

Spatial Distribution

The spatial distribution in Figures I-4, I-5, and I-6a through I-6j shows the following:

- Figure I-4 illustrates the distribution of samples for Iron King Mine tailings in the MTP for the combination of lead and zinc signatures. All of the samples have a ranking of “1”.
- Figure I-5 illustrates that samples strongly resembling Iron King Mine tailings (higher geochemical ranks) are continuously present along that path from the 1964 MTP Blow Out to Chaparral Gulch to the Tailings Floodplain to the dam. This figure illustrates that samples resembling Iron King Mine tailings are not present in the Smelter Tailings Swale.
- Figures I-6a and I-6b illustrate the Smelter materials in the Smelter Tailings Swale and the HSCD located at the mouth of the Smelter Tailings Swale do not resemble Iron King Mine tailings.
- Figures I-6c and I-6d illustrate the UCD and upper tailings classified as reworked that strongly resemble Iron King Mine tailings are continuously present along that path from the 1964 MTP Blow Out to Chaparral Gulch to the Tailings Floodplain to the dam.
- Figures I-6e and I-6f illustrate the lower tailings classified as undisturbed LCD are still impacted by materials resembling Iron King Mine tailings, but to a much lower degree than those of the UCD and tailings classified as reworked. This indicates that most tailings in these two deeper units originated from the former Humboldt Smelter property, although some are from Iron King Mine tailings. The signatures between the HSCD and the Humboldt Smelter tailings are similar to those of the tailings classified as undisturbed and the LCD.
- Figures I-6g through I-6j illustrate that the deeper materials (PFG, Brown Clay, Hickey Formation) deposited before operations at the former Iron King Mine and Humboldt Smelter properties began are not impacted by tailings.

Conclusions

The results of the statistical and spatial distribution analysis of the Iron King Mine tailings, Humboldt Smelter tailings, and deposits in the Chaparral Gulch floodplain upstream of the dam demonstrate the following:

- Mixtures of Iron King Mine tailings and Humboldt Smelter tailings have accumulated in the Chaparral Gulch floodplain upstream of the dam.
- There is a strong differentiation in geochemical signature between these two material groups that allows Iron King Mine tailings to be differentiated from Humboldt Smelter tailings. The lead and zinc concentrations and Zn:Cu and Pb:Cu ratios for the Iron King Mine tailings are significantly different than the ratios for Humboldt Smelter tailings. These ratios can be used to differentiate relative contribution of the Iron King Mine and Humboldt Smelter tailings in the impacted sediment of Chaparral Gulch upstream of the dam.
- Based on the geochemical analysis, the UCD and reworked tailings have substantial Iron King Mine source contributions, whereas the undisturbed tailings and LCD have a lower degree of Iron King Mine source contribution and appear more similar to materials from the Humboldt Smelter and HSCD. Iron King Mine tailings are continuously present along the path from the 1964 MTP Blow Out to Chaparral Gulch to the Tailings Floodplain to the dam. Iron King Mine tailings are not present in the Smelter Tailings Swale.

Notes:

Cu = Copper

HS = Humboldt Smelter

IKM = Iron King Mine

LCD = Lowermost Channel Deposit

mg/kg = milligrams per kilogram

Pb = Lead

PFG = Principle Fluvial Gravels

UCD = Uppermost Channel Deposit

Zn= Zinc

TABLE I-2

Wilcoxon Rank Sum Comparisons for Lead/Copper Ratios

Iron King Mine – Humboldt Smelter Superfund Site, Dewey-Humboldt, Yavapai County, Arizona

Wilcoxon Rank Sum Comparisons for Lead/Copper Ratios - IKM Tailings vs. Other Units

Grouping1	Grouping2	Parameter Considered	Probability that the Observed Differences Would Occur Purely by Chance	Statistical Decision with 0.05 Significance Level	Mean IKM Tailings	Mean Grouping2	Median IKM Tailings	Median Grouping2	Number of Mine Results	Number of Grouping2 Results
Materials Deposited after Iron King Mine and Humboldt Smelter began Operations										
IKM Tailings	HS Tailings	Lead/Copper Ratio	2.0E-12	Mine > Grouping2	35.3	1.93	11.5	1.73	40	31
